

PCC GARDENS MANAGER

Operational explainer

The complete unscheduled work system map

How ad-hoc requests, urgent jobs, infill and mulching enter operations—and when they consume capacity, alter route order or push recurring maintenance forward.

CORE PRINCIPLE

Raising work does not automatically move the schedule.

Team, date, time and an explicit capacity decision determine the operational impact.

01

What counts as unscheduled work?

It is an umbrella for work created outside the recurring maintenance generator. Each source enters the plan differently.

PLAN → INSERT

Infill or mulching

One-off operational work placed from Schedule or its programme workflow with an asset, team, date and estimated duration.

Appears alongside maintenance and is included in the shared day-capacity total.

02

Reactive requests: from report to field work

All creators enter the same controlled lifecycle. No role can create a request already completed or bypass the initial raised state.

Claim protection applies: another worker cannot overwrite or complete work already claimed by someone else.

03

The capacity decision

A date can contain recurring maintenance, active main-schedule jobs, infill and mulching. Productive minutes are the common budget.

04

Exactly how scheduled maintenance is affected

The system protects non-movable work. Only a deliberate push action changes recurring maintenance dates.

06

Where the work appears

Unscheduled work is merged into operational views, but its visibility depends on assignment, date and whether it is linked to an asset.
