

PCC GARDENS MANAGER

Operational explainer

The complete unscheduled work system map

How ad-hoc requests, urgent jobs, infill and mulching enter operations—and how an explicit capacity policy decides whether recurring maintenance gives way.

CORE PRINCIPLE

Unscheduled work gets a choice—not a blank cheque.

Team, date, time and an explicit precedence policy determine the operational impact.

01 What counts as unscheduled work? It is an umbrella for work created outside the recurring maintenance generator. Each source enters the plan differently.

02 Reactive requests: from report to field work All creators enter the same controlled lifecycle. No role can create a request already completed or bypass the initial raised state.

03 The capacity decision A date can contain recurring maintenance, active main-schedule jobs, infill and mulching. Productive minutes are the common budget—and precedence makes the trade-off explicit.

04 Exactly how scheduled maintenance is affected The default makes room carefully; the protected option leaves recurring work in place. Neither policy changes the geosequence rule.

05 Three insertion paths—and one precedence choice Where the work is created changes the review surface, but the same two capacity policies apply whenever an authorised manager or supervisor confirms team and date.

06 Where the work appears Unscheduled work is merged into operational views, but its visibility depends on assignment, date and whether it is linked to an asset.

OPERATIONAL RULE OF THUMB

Raised = queue only

Team + date = visible work

Minutes = capacity impact

Default = minimum room

Protected = choose / overload

Force = accepted overload

The mental model: unscheduled work enters operations; capacity determines whether it fits; the default makes minimum room from the route tail, while the protected option keeps scheduled work in place; route order remains the organising spine.
